This user manual provides information on running and using the UNICORE Gateway. Please note also the following places for getting more information:

UNICORE Website: https://www.unicore.eu Support list: unicore-support@lists.sf.net Developer's list: unicore-devel@lists.sf.net

1 Introduction

The Gateway is the entry point into a UNICORE site, routing HTTPS traffic to servers like UNICORE/X. It is installed in front of any networking firewall. It (optionally) authenticates incoming messages and forwards them to their intended destination. The Gateway receives the reply and sends it back to the client. In this way, only a single open port in a site's firewall has to be configured.

LIMITATIONS

This forwarding process only works for "most" HTTP requests, and is not a complete HTTP reverse proxy implementation. For example, it is not possible to run a full, complex web application like the UNICORE Portal "behind" the Gateway. Check the respective components's manual whether it can be run behind the Gateway.

In effect, traffic to a *virtual* URL, e.g. *https://mygateway:8088/Alpha* is forwarded to the real URL, e.g. *https://host1:7777*.

The mappings of virtual URL to real URL for the available sites are listed in a configuration file connections.properties. Additionally, the Gateway supports dynamic registration of sites.

The second functionality of the Gateway is (optional) authentication of incoming requests. Connections to the Gateway are made using SSL, so the Gateway can be configured to check whether the caller presents a certificate issued by a trusted authority. Information about the client is forwarded to services behind the Gateway in UNICORE proprietary format (as a SOAP or HTTP header).

The Gateway will forward the IP address of the client to the back-end server.

Last not least, the Gateway can be configured as a HTTP load balancer.

IMPORTANT NOTE ON PATHS

The UNICORE Gateway is distributed either as a platform independent and portable bundle (as a part of the UNICORE core server package) or as an installable, platform dependent package format such as RPM.

Depending on the installation method, the paths to various Gateway files are different. If installing using a distribution-specific package the following paths are used:

```
CONF=/etc/unicore/gateway
BIN=/usr/sbin
LOG=/var/log/unicore/gateway
```

If installing using the portable bundle all Gateway files are installed under a single directory. Path prefixes then are as follows, where INST is a directory where the Gateway was installed:

```
CONF=INST/conf
BIN=INST/bin
LOG=INST/log
```

The above variables (CONF, BIN and LOG) are used throughout the rest of this manual.

2 Installation

The UNICORE Gateway is distributed in the following formats:

- 1. As a part of platform independent installation bundle called UNICORE core server bundle. The UNICORE core server bundle is provided in two forms: one with a graphical installer and one with a command line installer.
- 2. As a binary, platform-specific package available currently for RedHat (Centos) and Debian platforms. Those packages are not tested on all possible platforms, but should work without any problems with other versions of similar distributions, e.g. SL6, Centos, or Fedora.

2.1 Installation from the core server bundle

Download the core server bundle from the UNICORE project website.

If you use the graphical installer, follow the on-screen instructions and do not forget to enable the Gateway checkbox when prompted.

If you use the console installer, please review the README file available after extracting the bundle. You don't have to change any defaults as the Gateway is installed by default.

2.2 Installation from a Linux package (rpm or deb)

Use your distribution's package manager to install.

3 Upgrading

The general update procedure is presented below, with possible variations:

- 1. Stop the old Gateway.
- 2. Update the server package. This step mostly applies for RPM/DEB managed installations. For Quickstart installation it is enough to replace the *.jar files with the new ones.
- 3. Start the newly installed Gateway.
- 4. Verify log file and fix any problems reported.

4 Configuration

The Gateway is configured using a set of configuration files, which reside in the CONF subdirectory.

4.1 Java and environment settings: startup.properties

This file contains settings related to the Java VM, such as the Java command to use, memory settings, library paths etc.

4.2 Configuring sites: connections.properties

This is a simple list connecting the names of sites and their physical addresses. An example is:

```
DEMO-SITE = https://localhost:7777
REGISTRY = https://localhost:7778
```

If this file is modified, the Gateway will re-read it at runtime, so there is no need to restart the Gateway in order to add or remove sites.

Optionally administrator can enable a possibility for dynamic site registration at runtime, see Section 4.3.3 for details. Then this file should contain only the static entries (or none if all sites register dynamically).

Further options for back-end sites configuration are presented in Section 6.

4.3 Main server settings: gateway.properties

Use the gateway.hostname property to configure the network interface and port the Gateway will listen on. You can also select between https and http protocol, though in almost all cases https will be used.

Example:

```
gateway.hostname = https://192.168.100.123:8080
```

Note

If you set the host to 0.0.0.0, the Gateway will listen on all network interfaces of the host machine, else it will listen only on the specified one.

If the scheme of the hostname URL is set to https, the Gateway uses the configuration data from security.properties to configure the HTTPS settings.

4.3.1 Credential and truststore settings

The Gateway credential and truststore is configured using the following properties

Property name	Type	Default	Description
		value /	
		mandatory	
gateway.credentia	1 filesystem path	mandatory to be set	Credential location. In case of <i>jks</i> , <i>pkcs12</i> and <i>pem</i> store it is the only location required. In case when credential is provided in two files, it is the certificate file path.
gateway.credentia	l [jks] pkest12, der, pem]	-	Format of the credential. It is guessed when not given. Note that <i>pem</i> might be either a PEM keystore with certificates and keys (in PEM format) or a pair of PEM files (one with certificate and second with private key).
gateway.credentia	l stpiag sword	-	Password required to load the credential.

Property name	Туре	Default	Description
		value /	
gateway.credentia	l etking Da+ h	mandatory	Location of the private key
gateway.credentia	T 2001 H Z L A C II	-	if stored separately from
			the main credential
			(applicable for <i>pem</i> and <i>der</i>
	_		types only),
gateway.credentia	l stræg Password	-	Private key password,
			which might be needed
			only for jks or pkcs12, if
			key is encrypted with
			different password then the
			main credential password.
gateway.credentia	l stkieg Alias	-	Keystore alias of the key
			entry to be used. Can be
			ignored if the keystore
			contains only one key entry.
			Only applicable for <i>jks</i> and
			pkcs12.

Property name	Type	Default	Description

4.3.2 Scalability settings

To fine-tune the operational parameters of the embedded Jetty server, you can set advanced HTTP server parameters. See [?informaltable] for details. Among others you can use the non-blocking IO connector offered by Jetty, which will scale up to higher numbers of concurrent connections than the default connector.

The Gateway acts as a https client for the VSites behind it. The number of concurrent calls is limited, and controlled by two parameters:

```
# maximum total number of concurrent calls to Vsites
gateway.client.maxTotal=100
# total number of concurrent calls per site
gateway.client.maxPerService=20
```

You can also control the limit on the maximum SOAP header size which is allowed by the Gateway. **Typically you don't have to touch this parameter**. However if your clients do produce very big SOAP headers and the Gateway blocks them, you can increase the limit. Note that such a giant SOAP header usually means that the client is not behaving in a sane way, e.g. is trying to perform a DoS attack.

```
# maximum size of an accepted SOAP header, in bytes
gateway.soapMaxHeader=102400
```

Note that Gateway may consume this amount of memory (plus some extra amount for other data) for each opened connection. Therefore, this value multiplied by the number of maximum allowed connections, should be significantly lower, then the total memory available for the Gateway.

4.3.3 Dynamic registration of Vsites

Dynamic registration is controlled by three properties in CONF/gateway.properties file:

```
gateway.registration.enable=true
gateway.registration.secret=<your key>
```

If set to true, the Gateway will accept dynamic registrations which are made by sending a HTTP POST request to the URL /VSITE_REGISTRATION_REQUEST This request must contain a parameter "secret" which matches the value configured in the gateway.properties file

Filters can be set to forbid access of certain hosts, or to require certain strings in the Vsite addresses. For example:

```
gateway.registration.deny=foo.org example.org
```

will deny registration if the remote hostname contains foo.org or example.org. Conversely,

```
gateway.registration.allow=mydomain.org
```

will only accept registrations if the remote address contains *mydomain.org*. These two (deny and allow) can be combined.

4.3.4 Web interface ("monkey page")

For testing and simple monitoring purposes, the Gateway displays a website showing detailed site information (the details view can be disabled). Once the Gateway is running, open up a browser and navigate to :8080">https://cgateway_host>:8080 (or whichever URL the gateway is running on). If the Gateway is configured to do SSL authentication, you will need to import a suitable client certificate into your web browser.

A HTML form for testing the dynamic registration is available as well, by clicking the link in the footer of the main Gateway page.

To disable the Vsite details page, set

gateway.disableWebpage=true

4.3.5 Main options reference

Property name	Туре	Default value / mandatory	Description
gateway.hostname	string	mandatory	external gateway bind
gateway.registrat		to be set	Space separated list of allowed hosts for dynamic registration.
gateway.registrat	i.stningleny	-	Space separated list of denied hosts for dynamic registration.
gateway.registrat	i [true⊋ fækse] e	false	Whether dynamic registration of sites is enabled.
gateway.registrat	i stning ecret	-	Required secret for dynamic registration.
	Passing Co	nsignor info	
gateway.consignor	TinkegeT≥meDTole	rânce	The validity time of the authenticated client information passed to backend sites will start that many seconds before the real authentication. It is used to mask time synchronization problems between machines.

Property name	Туре	Default	Description
		value / mandatory	
gateway.consignor	T inkegeV≥ ±ildity		What is the validity time of the authenticated client information passed to backend sites. Increase it if there machines clocks are not synhronized.
gateway.signConsi		false	Controls whether information about the authenticated client (the consignor) passed to backend sites should be signed, or not. Signing is slower, but is required when sites may be reached directly, bypassing the Gateway.
		Site client	
gateway.client.ch	u [tkædfalse]	true	Controls whether chunked passing of HTTP requests to backend sites is supported.
gateway.client.co	n integei onfibe re o	u £ 0000	Connection timeout, used when connecting to backend sites.
gateway.client.ex	p (trute¢ false) nue	true	Controls whether the HTTP expec-continue mechanism is enaled on connections to backend sites.
gateway.client.gz		true	Controls whether support for compression is announced to backend sites.
gateway.client.ke		true	Whether to keep alive the connections to backend sites.
gateway.client.ma		20	Maximum allowed number of connections per backend site.
gateway.client.ma	x integeit number	100	Maximum total number of connections to backend sites allowed.
gateway.client.so	c inntgei member	30000	Connection timeout, used when connecting to backend sites.

			require) client-side
			authentication.
gateway.httpServe	rstxingameAllow	ebolttp://lo	c Land Reference Reference to the control of the co
			to embed web interface
			inside a (i)frame.
			Meaningful only if the
			xFrameOptions is set to
			allowFrom. The value
			should be in the form:
			http[s]://host[:port]
gateway.httpServe		nosteny	Defines whether a
	sameOrigin,		clickjacking prevention
	allowFrom,		should be turned on, by
	allow]		insertionof the
			X-Frame-Options HTTP
			header. The <i>allow</i> value
			disables the feature. See the
			RFC 7034 for details. Note
			that for the <i>allowFrom</i> you
			should define also the
			xFrameAllowed option and
			it is not fully supported by
			all the browsers.

4.4 Require end-user certificates

In older versions of UNICORE, end-users were required to have client certificates. Since version 7, client certificates are optional. If you want to require end-user certificates, the Gateway can be configured accordingly. Set following in gateway.properties

gateway.httpServer.requireClientAuthn=true

4.4.1 Logging

The most important, root log categories used by the Gateway's logging are:

unicore.gateway	General Gateway logging
unicore.connections	Log IPs of clients, and the DN after the
	SSL handshake

unicore.httpserver	HTTP processing, Jetty server
unicore.security	Certificate details and other security

The Gateway uses the so called MDC (Mapped Diagnostic Context) to provide additional information on the client which is served. In the MDC the client's IP address and client's Distinguished Name is stored. You can control whether to attach MDC to each line by the %X{entry} log4j pattern entry. As the entry you can use: clientIP or clientName. For example:

```
log4j.appender.Al.layout.ConversionPattern=%d [%t] [%X{clientIP} %X \leftarrow {clientName}] %-5p %c{1} - %m%n
```

4.5 Logging

UNICORE uses the Log4j logging framework. It is configured using a config file. By default, this file is found in components configuration directory and is named logging.properties. The config file is specified with a Java property log4j.configuration (which is set in startup script).

Several libraries used by UNICORE also use the Java utils logging facility (the output is two-lines per log entry). For convenience its configuration is also controlled in the same logging.properties file and is directed to the same destination as the main Log4j output.

Note

You can change the logging configuration at runtime by editing the logging properties file. The new configuration will take effect a few seconds after the file has been modified.

By default, log files are written to the the LOGS directory.

The following example config file configures logging so that log files are rotated daily.

```
# Set root logger level to INFO and its only appender to A1.
log4j.rootLogger=INFO, A1

# A1 is set to be a rolling file appender with default params
log4j.appender.A1=org.apache.log4j.DailyRollingFileAppender
log4j.appender.A1.File=logs/uas.log

#configure daily rollover: once per day the uas.log will be copied
#to a file named e.g. uas.log.2008-12-24
log4j.appender.A1.DatePattern='.'yyyyy-MM-dd

# A1 uses the PatternLayout
log4j.appender.A1.layout=org.apache.log4j.PatternLayout
log4j.appender.A1.layout.ConversionPattern=%d [%t] %-5p %c{1} %x - 
%m%n
```

Note

In Log4j, the log rotation frequency is controlled by the DatePattern. Check http://logging.apache.org/log4j/1.2/apidocs/org/apache/log4j/DailyRollingFileAppender.html for the details.

For more info on controlling the logging we refer to the log4j documentation:

- PatternLayout
- RollingFileAppender
- DailyRollingFileAppender

Log4j supports a very wide range of logging options, such as date based or size based file rollover, logging different things to different files and much more. For full information on Log4j we refer to the publicly available documentation, for example the Log4j manual.

4.5.1 Logger categories, names and levels

Logger names are hierarchical. In UNICORE, prefixes are used (e.g. "unicore.security") to which the Java class name is appended. For example, the XUUDB connector in UNICORE/X logs to the "unicore.security.XUUDBAuthoriser" logger.

Therefore the logging output produced can be controlled in a fine-grained manner. Log levels in Log4j are (in increasing level of severity):

TRACE on this level *huge* pieces of unprocessed information are dumped, # DEBUG on this level UNICORE logs (hopefully) admin-friendly, verbose information, useful for hunting problems, # INFO standard information, not much output, # WARN warnings are logged when something went wrong (so it should be investigated), but recovery was possible, # ERROR something went wrong and operation probably failed, # FATAL something went really wrong - this is used very rarely for critical situations like server failure.

For example, to debug a security problem in the UNICORE security layer, you can set:

```
log4j.logger.unicore.security=DEBUG
```

If you are just interested in details of credentials handling, but not everything related to security you can use the following:

```
log4j.logger.unicore.security=INFO
log4j.logger.unicore.security.CredentialProperties=DEBUG
```

so the XUUDBAuthoriser will log on DEBUG level, while the other security components log on INFO level.

Note

(so the full category is printed) and turn on the general DEBUG logging for a while (on unicore). Then interesting events can be seen and subsequently the logging configuration can be fine tuned to only show them.

5 Using Apache httpd as a frontend

You may wish to use the Apache webserver (httpd) as a frontent for the Gateway (e.g. for security or fault-tolerance reasons).

Requirements

- · Apache httpd
- mod_proxy for Apache httpd

6 Using the Gateway for failover and/or loadbalancing of UNI-CORE sites

The Gateway can be used as a simple failover solution and/or loadbalancer to achieve high availability and/or higher scalability of UNICORE/X sites without additional tools.

A site definition (in ${\tt CONF/connections.properties}$) can be extended, so that multiple physical servers are used for a single virtual site.

An example for such a so-called multi-site declaration in the connections.properties file looks as follows:

```
#declare a multisite with two physical servers

MYSITE=multisite:vsites=https://localhost:7788 https://localhost ↔
:7789
```

This will tell the Gateway that the virtual site "MYSITE" is indeed a multi-site with the two given physical sites.

6.1 Configuration

Configuration options for the multi-site can be passed in two ways. On the one hand they can go into the connections.properties file, by putting them in the multi-site definition, separated by ";" characters:

```
#declare a multisite with parameters

MYSITE=multisite:param1=value1;param2=value2;param3=value3;...
```

The following general parameters exist

vsites	List of physical sites
strategy	Class name of the site selection strategy to
	use (see below)
config	Name of a file containing additional
	parameters

Using the "config" option, all the parameters can be placed in a separate file for enhanced readability. For example you could define in connections.properties:

```
#declare a multisite with parameters read from a separate file
MYSITE=multisite:config=conf/mysite-cluster.properties
```

and give the details in the file "conf/mysite-cluster.properties":

```
#example multisite configuration
vsites=https://localhost:7788 https://localhost:7789

#check site health at most every 5 seconds
strategy.healthcheck.interval=5000
```

6.2 Available Strategies

A selection strategy is used to decide where a client request will be routed. By default, the strategy is "Primary with fallback", i.e. the request will go to the first site if it is available, otherwise it will go to the second site.

Primary with fallback

This strategy is suitable for a high-availability scenario, where a secondary site takes over the work in case the primary one goes down for maintenance or due to a problem. This is the default strategy, so nothing needs to be configured to enable it. If you want to explicitly enable it anyway, set

```
\verb|strategy=primaryWithFallback||
```

The strategy will select from the first two defined physical sites. The first, primary one will be used if it is available, else the second one. Health check is done on each request, but not more frequently as specified by the "strategy.healthcheck.interval" parameter. By default, this parameter is set to 5000 milliseconds.

Changes to the site health will be logged at "INFO" level, so you can see when the sites go up or down.

Round robin

This strategy is suitable for a load-balancing scenario, where a random site will be chosen from the available ones. To enable it, set

```
strategy=roundRobin
```

Changes to the site health will be logged at "INFO" level, so you can see when the sites go up or down.

It is very important to be aware that this strategy requires that all backend sites used in the pool, share a common persistence. It is because Gateway does not track clients, so particular client requests may land at different sites. This is typically solved by using a non-default, shared database for sites, such as MySQL.

Note

Currently loadbalancing of target sites is an experimental feature and is not yet fully functional. It will be improved in future UNICORE versions.

Custom strategy

You can implement and use your own failover strategy, in this case, use the name of the Java class as strategy name:

```
strategy=your_class_name
```

7 Gateway failover and migration

The Section 6 covered usage of the Gateway to provide failover of backend services. However it may be needed to guarantee high-availabilty for the Gateway itself or to move it to other machine in case of the original one's failure.

7.1 Gateway's migration

The Gateway does not store any state information, therefore its migration is easy. It is enough to install the Gateway at the target machine (or even to simply copy it in the case of installation

from the core server bundle) and to make sure that the original Gateway's configuration is preserved.

21

If the new machine uses a different address, it needs to be reflected in the server's configuration file (the listen address). Also, the configuration of sites behind the Gateway must be updated accordingly.

7.2 Failover and loadbalancing of the Gateway

Gateway itself doesn't provide any features related to its own redundancy. However as it is stateless, the standard redundancy solutions can be used.

The simpliest solution is to use Round Robin DNS, where DNS server routes the Gateway's DNS address to a pool of real IP addresses. While easy to set up this solution has a significant drawback: DNS server doesn't care about machines being down.

The much better choice is to use the Linux-HA software suite, often known under the name of its principal component, the *heartbeat*. For details see http://www.linux-ha.org

Additionally a more advanced HTTP-aware software can be used, such as HA-Proxy (http://haproxy.1wt.eu). Currently Gateway and UNICORE don't maintain HTTP sessions so usage of the HTTP-aware load-balancer is not strictly required, but such solutions generally provide more general purpose features.

8 Building the Gateway from source

To checkout the latest version of the Gateway source code, do

```
svn co http://svn.code.sf.net/p/unicore/svn/gateway/trunk gateway
```

You will need to install Maven from http://maven.apache.org Compile using

```
mvn install
```

which compiles the code and runs the tests.

The file "README-building.txt" contains instructions for building distributable packages.
