This is the UFTPD user manual providing information on running and using the UNICORE UFTP server *uftpd*. Please note also the following places for getting more information:

UNICORE Website: http://www.unicore.eu

Support list: unicore-support@lists.sf.net

Developer's list: unicore-devel@lists.sf.net

UFTP issue tracker: https://sourceforge.net/p/unicore/uftp-issues

1 UNICORE UFTP

UFTP is a data streaming library and file transfer tool.

It can be used integrated into UNICORE, allowing to transfer data from client to server (and vice versa), as well as providing data staging between UFTP-enabled UNICORE sites. UFTP can also be used independently from UNICORE, requiring a authentication server and a standalone UFTP client.

A full UFTP server installation consists of two parts

- the "uftpd" file server
- either a UNICORE/X server, or a standalone authentication service.

This manual covers the UFTP file server "uftpd".

1.1 UFTP features

- dynamic firewall port opening using a pseudo FTP connection. UFTPD requires only a single open port.
- parallel input/output streams based on code from the JPARSS library, Copyright (c) 2001 Southeastern Universities Research Association, Thomas Jefferson National Accelerator Facility
- optional encryption of the data streams using a symmetric key algorithm
- optional compression of the data streams (using gzip)
- command port protected by SSL
- partial reads/writes to a file. If supported by the filesystem, multiple UFTP processes can thus read/write a file in parallel (striping)
- supports efficient synchronization of single local and remote files using the rsync algorithm
- integrated into UNICORE clients for fast file upload and download

- · integrated with UNICORE servers for fast data staging and server-to-server file transfers
- standalone (non-UNICORE) client available
- data upload/download with curl or ftp possible in conjunction with the auth server
- written in Java

1.2 How does UFTP work

The UFTP file server, called *uftpd*, listens on two ports (which may be on two different network interfaces):

- the command port receives control commands
- the listen port accepts data connections from clients.

The uftpd server is "controlled" (usually by UNICORE/X) via the command port, and receives/sends data directly from/to a client machine (which can be an actual user client machine or another server). Data connnections are made to the "listen" port, which has to be accessible from external machines. Firewalls have to treat the "listen" port as an FTP port.

A UFTP file transfer works as follows:

- the UNICORE/X server sends a request to the command port. This request notifies the UFTPD server about the upcoming transfer and contains the following information
 - a "secret", i.e. a one-time password which the client will use to authenticate itself
 - the user and group id which uftpd should use to access files
 - an optional key to encrypt/decrypt the data
 - the client's IP address
- the UFTPD server will now accept an incoming connection from the announced IP address, provided the supplied "secret" matches the expectation.
- if everything is OK, an FTP session is created, and the client can use the FTP protocol to open data connections, list files, transfer data etc. Firewall transversal will be automatic using passive FTP (see below for alternatives like using a fixed port range).
- to access requested files, uftpd attempts to switch its user id to the requested one prior to reading/writing the file. This uses a C library which is accessed from Java via the Java native interface (JNI). See also the installation section below.

[NOTE] .IMPORTANT SECURITY NOTE

The UNICORE UFTPD server is running with root privileges. Make sure to read and understand the section below on protecting the command socket. Otherwise, users logged on to the UFTPD machine can possibly read and write other user's files.

2 Installation and use

2.1 Prerequisites

- Java 8 (or later) runtime is required
- the server "listen" port needs to be accessible through your firewalls, declaring it an "FTP" port (FTP connection tracking). Alternatively a fixed range of open ports can be configured and used
- the UFTPD server needs access to the target file systems
- a server certificate for the UFTPD server is STRONGLY recommended for production use (see the section on SSL below)

A functional UFTP installation requires either a full UNICORE/X server or the auth server.

NOTE ON PATHS

The UNICORE UFTPD server is distributed either as a platform independent and portable tar.gz or zip bundle, or as an installable, platform dependent package such as RPM. Depending on the installation package, the paths to various files are different. If installing using distribution-specific package the following paths are used:

```
CONF=/etc/unicore/uftpd
SBIN=/usr/sbin
BIN=/usr/bin
LOG=/var/log/unicore/uftpd
LIB=/usr/share/unicore/uftpd/lib
```

If installing using the portable bundle, all UFTPD files are installed under a single directory. Path prefixes are as follows, where INST is the directory where UFTPD was installed:

```
CONF=INST/conf
SBIN=INST/bin
BIN=INST/bin
LOG=INST/log
LIB=INST/lib
```

These variables (CONF, SBIN, BIN and LOG) are used throughout the rest of this manual.

2.2 C library for switching user ID

It may be required to re-compile the libuftp-unix.so library on your system. This library uses the Java Native Interface (JNI). The version supplied with the distribution has been compiled on a 64bit Linux system. The folder LIB/native contains the required headers and C source files, as well as an exemplary makefile. Please edit the makefile, the following information is required:

- the base directory of our Java installation (JAVA_HOME)
- the location of platform-specific include files
- the location of the uftp-<version>.jar file (LIB)

Then, run "make install" to build the library, which will compile the code and install the library into the LIB folder. If any problems occur during this procedure, please consult UNICORE support.

2.3 Starting and stopping the UFTPD server

In the SBIN directory, start/stop and status scripts are provided:

- unicore-uftpd-start.sh starts the server
- unicore-uftpd-stop.sh stops the server
- unicore-uftpd-status.sh checks the server status

The parameters such as server host/port, control host/port, and others are configured in the CONF/uftpd.conf file

In a production scenario with multiple users, the uftpd server needs to be started as root. This is necessary to be able to set the correct file permissions.

2.4 Configuration parameters

The following variables can be defined in the configuration file (uftpd.conf):

SERVER_HOST client data	: the interface where the server listens for \hookleftarrow
	connections
SERVER_PORT client data	: the port where the server listens for $ \leftarrow $
offene adda	connections
ADVERTISE_HOST following IP	: Advertise this server as having the $ \leftrightarrow $ in the
	control connection. This is useful if the $ \leftrightarrow $ server is behind
	a NAT firewall and the public address is $ \hookleftarrow $ different from
	SERVER_HOST.

- CMD_HOST : the interface where the server listens for \leftarrow control commands
- CMD_PORT : the port where the server listens for $\, \hookleftarrow \,$ control commands
- SSL_CONF : File containing SSL settings for the $\, \leftarrow \,$ command port
- ACL : File containing the list of server DNs ↔ that are allowed access to the command port
- UFTPD_MEM : the maximum memory (Java heap size) $\, \hookleftarrow \,$ allocated to the UFTPD server
- <code>MAX_CONNECTIONS</code> : the maximum number of concurrent control $\ \leftrightarrow$ connections per client IP
- <code>MAX_STREAMS</code> : the maximum number of parallel TCP streams \hookleftarrow per connection
- BUFFER_SIZE : the size of the buffer (in kilobytes) for ↔
 reading/writing local files
- PORT_RANGE : (optional) server-side port range in the ↔
 form 'lower:upper' that will be
 used for data connections. By default, any ↔
 free ports will be used.
 Example: set to '50000:50500' to limit the ↔
 port range.
 NOTE ports in this range *must not* be ↔
 used by other services!
- DISABLE_IP_CHECK : (optional) in some situations, the client ↔ IP can be different from the one that was sent to the UFTPD server ↔ . This will lead to rejected transfers. Setting this variable to a non ↔ -zero value will disable the IP check. Only the one-time password will ↔ be checked.

As usual if you set the SERVER_HOST to be "0.0.0.0", the server will bind to all the available network interfaces.

If possible, use an "internal" interface for the Command socket. If that is not possible, make sure the Command socket is protected by a firewall!

We STRONGLY recommend enabling SSL for the Command socket. Please refer to the next section.

2.5 Protecting the Command socket

Using SSL for the Command port ensures that only trusted parties (i.e. trusted UNICORE servers) can issue commands to the UFTPD server. To further limit the set of trusted users, an access control list (ACL) file is used.

In production settings where users can log in to the UFTPD server machine, SSL MUST be enabled to prevent unauthorized data access!

[NOTE] .IMPORTANT SECURITY NOTE

Without SSL enabled, users logged in to the UFTPD server can easily create exploits to read or write files with arbitrary user privileges (except *root*).

2.5.1 SSL setup

To setup SSL, you need a keystore containing the UFTPD server's credential, and a truststore containing certificate authorities that should be trusted. Keystore and truststore can be the same file.

The following properties can be set in the CONF/uftpd-ssl.conf file.

Property name	Туре	Default	Description
		value /	
		mandatory	
credential.path	filesystem path	mandatory	Credential location. In case
		to be set	of <i>jks</i> , <i>pkcs12</i> and <i>pem</i> store
			it is the only location
			required. In case when
			credential is provided in
			two files, it is the certificate
			file path.

 Table 1: Credential properties

Property name	Туре	Default value / mandatory	Description
credential.format	[jks, pkcs12, der, pem]	-	Format of the credential. It is guessed when not given. Note that <i>pem</i> might be either a PEM keystore with certificates and keys (in PEM format) or a pair of PEM files (one with certificate and second with private key).
credential.passwo	rstring	-	Password required to load the credential.
credential.keyPat	hstring	-	Location of the private key if stored separately from the main credential (applicable for <i>pem</i> and <i>der</i> types only),
credential.keyPas	s stoing	-	Private key password, which might be needed only for <i>jks</i> or <i>pkcs12</i> , if key is encrypted with different password then the main credential password.
credential.keyAli	a string	-	Keystore alias of the key entry to be used. Can be ignored if the keystore contains only one key entry. Only applicable for <i>jks</i> and <i>pkcs12</i> .

Table 2: Truststore properties

Property name	Туре	Default value / mandatory	Description
truststore.allowP	r [Aklj/LOW, DENY]	ALLOW	Controls whether proxy certificates are supported.
truststore.type	[keystore, openssl, directory]	mandatory to be set	The truststore type.

Property name	Туре	Default	Description
		value /	-
		mandatory	
truststore.update	I integev aumber	600	How often the truststore should be reloaded, in seconds. Set to negative value to disable refreshing at runtime. (<i>runtime</i> <i>updateable</i>)
		ype settings	
truststore.direct			Connection timeout for fetching the remote CA certificates in seconds.
truststore.direct	ofilei3yistèrn pathe⊺	ath	Directory where CA certificates should be cached, after downloading them from a remote source. Can be left undefined if no disk cache should be used. Note that directory should be secured, i.e. normal users should not be allowed to write to it.
truststore.direct		PEM *-	For directory truststore controls whether certificates are encoded in PEM or DER. Note that the PEM file can contain arbitrary number of concatenated, PEM-encoded certificates. List of CA certificates locations. Can contain
	a common prefix		URLs, local files and wildcard expressions. (<i>runtime updateable</i>)
	Kevstore ty	pe settings	
truststore.keystc		-	The keystore type (jks, pkcs12) in case of truststore of keystore type.
truststore.keysto	_	-	The password of the keystore type truststore.
truststore.keysto	r stPiag h	-	The keystore path in case of truststore of keystore type.

Property name	Туре	Default	Description
		value /	-
		mandatory	
	Openssl t	vpe settings	
truststore.oper	nssl (teve \$fadse)Form	mafalse	In case of openssl
			truststore, specifies whether
			the trust store is in openssl
			1.0.0+ format (true) or
			older openssl 0.x format
			(false)
truststore.open	nssl MGMOB&US_EUG	RHDRMADPM	Lancase of openssl
	EU-		truststore, controls which
	GRIDPMA_GL0	OBUS,	(and in which order)
	GLOBUS,		namespace checking rules
	EUGRIDPMA,		should be applied. The
	GLOBUS_EUG	RIDPMA_REQ	U RHQ UIRE settings will
	EU-		cause that all configured
	GRIDPMA_GL0	BUS_REQUI	REnamespace definitions files
	GLOBUS_REQU	JIRE,	must be present for each
	EU-		trusted CA certificate
	GRIDPMA_REC	UIRE,	(otherwise checking will
	EU-		fail). The AND settings will
	GRIDPMA_AN	D_GLOBUS,	cause to check both existing
	EU-		namespace files. Otherwise
	GRIDPMA_AN	D_GLOBUS_R	EQNE III Found is checked
	IGNORE]		(in the order defined by the
			property).
truststore.oper	nssl fikesystem path	/etc/grid	d-Directoriyty / beaused for cates
			opeenssl truststore.
		on settings	
truststore.crl	Conn entegeonümber or	ut15	Connection timeout for
			fetching the remote CRLs
			in seconds (not used for
			Openssl truststores).

Property name	Туре	Default	Description
		value /	
truststore.crlD	isk ûkesýstem path	mandatory -	Directory where CRLs should be cached, after
			downloading them from
			remote source. Can be left undefined if no disk cache
			should be used. Note that
			directory should be secured, i.e. normal users
			should not be allowed to
			write to it. Not used for
truststore.crlL	ocatistants +	_	Openssl truststores. List of CRLs locations. Can
CIUSCSCOLE.CIIL	properties with		contain URLs, local files
	a common		and wildcard expressions.
	prefix		Not used for Openssl truststores. (<i>runtime</i>
			updateable)
truststore.crlM		IF_VALID	General CRL handling
	IF_VALID, IGNORE]		mode. The IF_VALID setting turns on CRL
	IONOREJ		checking only in case the
			CRL is present.
truststore.crlU	pda integet eurober	600	How often CRLs should be
			updated, in seconds. Set to negative value to disable
			refreshing at runtime.
<u> </u>	a 1 (m) 1 1	2.600	(runtime updateable)
truststore.ocsp	Cacimedger number	3600	For how long the OCSP responses should be locally
			cached in seconds (this is a
			maximum value, responses
			won't be cached after expiration)
truststore.ocsp	Dis filesystem path	-	If this property is defined
			then OCSP responses will be cached on disk in the
			defined folder.
truststore.ocsp		<number></number>	Optional list of local OCSP
	properties with		responders
	a common prefix		
	PICITY	I	1

Property name	Туре	Default	Description
		value /	
		mandatory	
truststore.ocspMo	d {REQUIRE ,	IF_AVAILA	BGeneral OCSP ckecking
	IF_AVAILABLE,		mode. REQUIRE should
	IGNORE]		not be used unless it is
			guaranteed that for all
			certificates an OCSP
			responder is defined.
truststore.ocspTi	minteger number	10000	Timeout for OCSP
			connections in miliseconds.
truststore.revoca	t [GRD<u>r</u>GESP ,	OCSP_CRL	Controls overal revocation
	OCSP_CRL]		sources order
truststore.revoca	t [itcure() faelse] 1	false	Controls whether all
			defined revocation sources
			should be always checked,
			even if the first one already
			confirmed that a checked
			certificate is not revoked.

If the credential.path property is NOT set, SSL will be disabled.

[NOTE] .Backwards compatibility to previous versions

Existing configuration files with the <code>javax.net.ssl.*</code> properties used in UFTPD < 2.6 are still supported

2.5.2 ACL setup

The access control list contains the distinguished names of those certificates that should be allowed access.

The "ACL" setting in CONF/uftpd. conf is used to specify the location of the ACL file

export ACL=conf/uftpd.acl

The default ACL contains the certificate DN of the UNICORE/X server from the UNICORE core server bundle. In production, you need to replace this by the actual DNs of your UNI-CORE/X server(s) and UFTP Authentication server(s).

The ACL entries are expected in RFC2253 format. To get the name from a certificate in the correct format using openssl, you can use the following OpenSSL command:

```
$> openssl x509 -in your_server.pem -noout -subject -nameopt ↔
RFC2253
```

The ACL file can be updated at runtime.

2.6 Firewall configuration

Note

Please consult the firewall documentation on how to enable an "FTP" service on your firewall (or operating system).

With Linux iptables, you may use rules similar to the following:

```
iptables -A INPUT -p tcp -m tcp --dport $SERVER_PORT -j ACCEPT
iptables -A INPUT -p tcp -m helper --helper ftp-$SERVER_PORT -j ↔
ACCEPT
```

where \$SERVER_PORT is the SERVER_PORT defined in uftpd.conf. The first rule allows anyone to access port \$SERVER_PORT. The second rule activates the iptables connection tracking FTP module on port \$SERVER_PORT.

On some operating systems it may be required to load additional kernel modules to enable connection tracking, for example on CentOS:

```
modprobe nf_conntrack_ipv4
modprobe nf_conntrack_ftp ports=$SERVER_PORT
```

2.7 Logging

UFTPD uses log4j, the same logging system as other UNICORE components. Logging is configured in the CONF/logging.properties file.

Note

You can change the logging configuration at runtime by editing the logging.properties file. The new configuration will take effect a few seconds after the file has been modified.

By default, log files are written to the the LOG directory.

For more info on controlling the logging we refer to the log4j documentation:

PatternLayout

- RollingFileAppender
- DailyRollingFileAppender

Log4j supports a very wide range of logging options, such as date based or size based file rollover, logging different things to different files and much more. For full information on Log4j we refer to the publicly available documentation, for example the Log4j manual.

2.7.1 Logger categories, names and levels

Logger names are hierarchical. Prefixes are used (e.g. "uftp.server") to which the Java class name is appended.

The logging output produced can be controlled in a fine-grained manner. Log levels in Log4j are (in increasing level of severity) TRACE, DEBUG, INFO, WARN, ERROR, and FATAL.

For example, to track the UFTPD server's communication with clients in detail, you can set

log4j.logger.uftp.server=DEBUG

Here is a table of logger categories

Log category	Description	
uftp	All UFTP logging	
uftp.security	Security	
uftp.server	Server code	
uftp.client	Client code	

Note

Please take care to not set the global level to TRACE or DEBUG for long times, as this may produce a lot of output.

2.7.2 Usage logging

Often it is desirable to keep track of the usage of your UFTPD server. The server has a special logger category which logs information about finished jobs at INFO level. If you wish to enable this, set the level to INFO or higher:

log4j.logger.uftp.server.USAGE=INFO

3 UNICORE Integration

In UNICORE, UFTP can be used for uploading/downloading data from a server, as well as server-to-server transfers, where one UNICORE/X instance acts as UFTP client.

To enable a UNICORE/X server for the UFTP filetransfer the following settings have to be made.

3.1 Configuring the UFTP service

The UNICORE/X server needs to know the UFTPD server settings (i.e. host and port of both the command and the main listener socket). If the coreServices.uftp.server.host property is set, UFTP will be enabled and advertised to clients.

In the uas.config file, the following properties are mandatory for UFTP:

```
#
# REQUIRED parameters
#
# Listener (pseudo-FTP) socket
coreServices.uftp.server.host=...
coreServices.uftp.server.port=...
# Command socket
coreServices.uftp.command.host=...
coreServices.uftp.command.port=...
#
#
# Full path to the 'uftp.sh' client executable
# on the TSI login node
#
coreServices.uftp.client.executable=...
```

There are further configuration options to tune how UFTP behaves

```
#
# Optional parameters
#
# How many parallel streams to use per file transfer
coreServices.uftp.streams=1
# Limit the maximum number of streams per file transfer
coreServices.uftp.streamsLimit=4
```

3.2 UFTPD servers with multiple interfaces

If your UFTPD server is on a machine with multiple network interfaces, you can give a commaseparated list of host names, like so:

```
coreServices.uftp.server.host=net1.domain.org,net2.domain.org
```

The UFTP client in this case will try to connect to the hosts in the specified order, and will use the first "working" one.

3.3 Enabling data encryption

If you wish to encrypt the data sent/received by UFTPD (in data staging or server-to-server transfers), the following property can be used:

```
# enable data encryption
coreServices.uftp.encryption=true
```

This will by default encrypt data with a symmetric key using the Blowfish algorithm. This costs some performance due to the additional CPU load. Encryption only works in single-stream mode. Users can override this setting.

3.4 Limiting bandwidth per transfer

It is possible to limit the bandwidth that is consumed by a single UFTP transfer. It is given in bytes per second.

```
# limit transfer rate (bytes/second)
coreServices.uftp.rateLimit=10000000000
```

3.5 Disabling SSL on the command port

While not recommended, it may be sometimes useful to disable SSL for communicating with the UFTPD, e.g. while setting up and testing. To do this add a property in uas.config (no UNICORE/X restart is required)

```
coreServices.uftp.command.sslDisable=true
```

3.6 Enabling "local" UFTP mode on the UNICORE/X server

In case the UNICORE/X server has direct access to the target file system, and you're not using the UNICORE TSI, it can be an interesting option to run the UFTP filetransfer client code directly in the UNICORE/X server instead of passing it to the TSI. This means more load in the UNICORE/X process. It is also a way to use UFTP to/from a UNICORE/X server running on Windows. To enable local mode, edit uas.config and set

enable local client mode
coreServices.uftp.client.local=true

4 Testing the UFTPD server

Testing as described in this section works only if SSL is not enabled. Therefore, you should run these tests as a non-root user. Enable SSL and restart the UFTPD server with root privileges once you are finished with these tests.

The UFTPD distribution contains two scripts that allow you to test the UFP functionality without using any external servers or clients. Making a data transfer involves two steps:

- invoke uftp-job.sh to "announce" an upcoming transfer to the UFTPD server
- invoke uftp.sh to initiate the actual transfer

Note, in case you installed from an RPM or DEB package, these files are located in /usr/bin.

The following shell commands "transfer" the file .bashrc to the /tmp directory.

Assuming you installed from RPM/DEB:

```
. /etc/unicore/uftpd/uftpd.conf
uftp-job.sh -c localhost -f ~/.bashrc -s true -x my_secret -n 2 -u ↔
unicore -g unicore
uftp.sh -r -f /tmp/test -L $SERVER_PORT -l $SERVER_HOST -x ↔
my_secret -n 2
```

This should create a file /tmp/test identical to ~/.bashrc. Check the console output and the UFTPD log file LOG/uftpd.log in case of errors.

After the transfer finished, check that indeed

md5sum /tmp/test ~/.bashrc

gives the correct checksum for the newly created file.

It is also possible to enable encryption "manually", by appending "-E <key>" to the commands above, where "key" is a sequence of 12 characters (really a base64-encoded 64 bit key).

5 Performance measurement hints

To run performance tests, it is possible to read and write from/to pseudo files in "/dev". Since UFTP needs to know the number of bytes to transfer, this can be given using a "pseudo" file-name. For example, you could read from "/dev/zero_<number_of_bytes>" and write to "/de-v/null".

UFTP will treat any filename that starts with "/dev" and contains an underscore "_" character in this manner.

For example, to transfer a gigabyte of zeros to /dev/null,

```
. /etc/unicore/uftpd/uftpd.conf
uftp-job.sh -c localhost -f /dev/zero_1000000000 -s true -x ↔
my_secret -n 2 -u unicore -g unicore
uftp.sh -r -f /dev/null -L $SERVER_PORT -1 $SERVER_HOST -x ↔
my_secret -n 2
```
